ABSTRACT

Background: The study was designed to identify the role of local exogenous green tea in bone healing.

Material and method: Thirty male albino rats, were subjected for bone defects in medial sides of both tibia bone (right tibia was considered as experimental site with 1µl of extract green tea, while the left be the control one, treated with 1µl of normal saline). The rats were scarified at 3,7,10 days post surgery. Bone healing was histologically examined with immunohistochemical for localization of bone morphogenic protein 2.

Results: show bone healing treated with extracted green tea illustrated to be faster in apposition of ostoid and bone trabeculae that is detected to fill the most of bone defect in comparism with control group.

Conclusion: Our results indicate that low application of exogenous green tea could be an effective therapeutic for bone injures, these data are promising for a possible future clinical usage especially for enhancement of bone healing.

INTRODUCTION

Bone is a composition tissue that consists of organic components, type I collagen, non collagenous proteins and in organic components, mainly hydroxyapatite crystals (Nanci, et al., 2008). The two main categories of bone cells are osteoblasts that form the bone and osteoclasts that resorb (dissolve) the bone. The combined and cooperative activities of osteoblasts and osteoclasts result in a bone architecture that provides mechanical support and protection for the body. In addition, bone serves as a vital reservoir of minerals, principally calcium and phosphorus, necessary for maintaining normal cellular, neurologic, and vascular activities of the body (Nijweide et al., 2010).

Both osteoblastic and osteoclastic cells regulate bone metabolism, and both cell types are involved in the development of osteoporosis (Nijweide et al., 2010). Osteoblasts, the bone-forming cells, locate near the surface of the bone and produce cytokines that affect osteoclasts. Viable osteoblasts acting in concert with multiple growth factors (Matsuo et al., 2008), which are essential for the repair and regeneration of bone. Specific growth factors important to bone formation include fibroblast growth factor 2, platelet-derived growth factor, vascular endothelial growth factor, Insulin like growth factor, bone morphogenic protein 2,4 and 7, and transforming growth factor-beta (Singer et al.,2011).

Tea, the dried leaves of the Camellia sinensis species of the Theaceae family, is a popular beverage with an annual production of three billion kilograms worldwide (Yang et al., 2000). In the past decade, epidemiological evidence has shown an association between tea consumption and the prevention of age-related bone loss in the elderly population. The objective of this research is to study the benefits of local application of green tea as exogenous biomaterial on bone healing. As the use of green tea is a first trial to study in healing process.

Green tea polyphenols (GTP) have positive effects on bone mass and microarchitecture in both models of bone loss (She et al., 2008; Shen et al., 2009). Green tea prevented the aging-induced as well as aging plus estrogen deficiency-induced reduction in femoral bone mass (i.e., bone mineral content (BMC) and density (BMD), respectively (Chwan-Li et al., 2011). Serum osteocalcin (a bone formation biomarker) was elevated by the GTP treatment, while serum tartrate-resistant acid phosphatase (TRAP, a bone resorption biomarker) was suppressed by the GTP treatment (Wang et al., 2008).

Green tea polyphenols supplementation was shown to suppress oxidative stress (as shown by decreased urinary 8-hydroxy-2′-deoxyguanosine levels) and inflammation (as shown by suppressed mRNA expression of tumor necrosis factor-α and cyclooxygenase-2 in spleen). Authors concluded that GTP mitigates bone loss in a chronic-inflammation-induced bone loss model by reducing oxidative stress-induced damage and inflammation (Shen et al., 2009; Shen et al.,2010).

One particular green tea compound called Epi-gallo-catechin (EGC), led to an increase in this enzyme’s activity by 79%. It also increased levels of bone mineralization in these cells: a vital part of strengthening bones (Mount et al.,2006).

Epi-gallo-catechin also suppressed the activity of cells called osteoclast cells that weaken and break down old bone, part of the natural process of bone
remodelling. (Choi et al.,2003).

**MATERIALS AND METHODS**

The study was designed to illustrate the effectiveness of application of the local exogenous extracted green tea gel by studying bone specimens histologically and identification of bone morphogenic protein 2 in bone tissue.

All experimental procedures were carried out in accordance with ethical principles of animal experimentation.

**Experimental animals**

In this research, thirty male albino rats, weighing (320-500) gram, aged (6.5-8) months were used and maintained under control conditions of temperature, drinking and food consumption.

The animals were subjected for bone defects in medial sides of both tibial bone ( right tibia was considered as experimental site, while left be the control one), the animals were divided into two groups:

1. Control group: the bone defect treated with 1µl normal saline.
2. Experimental group: includes 10 rats, the bone defect treated with 1µl extracted green tea gel.

The rats were sacrificed at 3, 7, 10 days post surgery.

**Materials**

Extracted green tea gel

**Methods**

The animals were subjected for a surgical operation. The surgery was performed under a well sterilized condition and gentle technique. Every animal was weighted to calculate the dose of general anesthesia that was given to it. The general anesthesia was induced by Intra muscular injection of xylazine 2% (0.4 mg/kg B.W.), plus ketamine HCL 50mg (40 mg/kg- B.W.also an antibiotic cover with oxy-tetracycline 20% ( 0.7 ml/kg) intramuscular injection was given. Then the animal was placed on the surgical table and the surgical towel was placed under the site of the operation. Both tibiae were shaved using cream from the inner side and the skin was cleaned with a mixture of ethanol and iodine then a piece of cotton damped with alcohol and left covering the shaved skin for one minute . Surgery was performed under sterile condition and gentle surgical technique. The cotton was removed. Incision was made on the lateral side to expose the medial side of the tibia , the skin and fascia flap was reflected. By intermittent drilling, and continuous cooling with irrigated saline, ahole of 1.8mm was made with small round bur. Bone penetration was performed at a rotary speed of 1500 rpm. Following the hole preparation, the operation site was washed with saline solution to remove debris from the drilling site. Bone defect was made on both medial sides of right and left tibia bone, experimental and control sites.

After operation drying the area by air, then applied extracted green tea gel1µl .While normal saline 1 µml was used for control. Suturing of the muscles was done with absorbable catgut followed by skin suture . The operation site was sprayed with local antibiotic (tetracycline spray), also long acting systemic antibiotic oxy-tetracycline 20% (0.7 ml/1kg) was given to the animals after the surgery. Post operative care was performed by giving an antibiotic ( local and systemic). The animals were scarified at intervals 3,7,10 day , using over dose anesthesia . Five animals for each period, for each group. The tibia bone was dissected and fixed in10% buffered formalin. Histological examination was done for all samples under light microscope.

**Assessment for immunohistochemistry results**

Positive reading was indicated when the cells display a brown cytoplasmic stain, while negative reading was indicated for absence of immune reactions depends on positive and negative control.

**Immunohistochemical scoring of BMP2**

Quantification method of Immunoreactivity was semiquantitatively estimated the immune-staining score that was calculated as the sum of a proportion score . The proportion score reflects the estimated fraction of positively stained infiltrating cells:

- score 0: none.
- score 1:<10%.
- score 2:10-50%.
- score 3:51-80%.
- score 4: >80%.

The intensity score represents the estimated staining intensity (score0, no staining, score1weak, score2 moderate, score3 strong), Hillmann et al.,1999.

**RESULTS**

**Histological findings**

Control group at 3 Days duration shows bone marrow infiltrated by inflammatory cells with newly formed blood vessels; (Figure 1). Bone healing site for Control 7 Days duration shows fibrous tissue, with progenitor cell and fibroblast cell; (Figures 2). Trabeculated bone coalesce with cutting bone. Osteoblast, osteocyte and reticular cells aew detected at 10 day post operative period ( Figures 3,4).

**Figure 3.1** Microphotograph view for control group (3 days) shows progenitor cell (arrow head), inflammatory cell (arrow).H&EX20
Figure 2: View for bone healing site (control 7 days) shows fibrous tissue (FT) with progenitor cell (arrow head), fibroblast (arrow). H&EX20

Figure 3: View for trabeculated bone (TB) coalesce with cutting bone (CB) in control group 10 days. H&EX20

Figure 4: View for osteoid tissue (OT) filled the bone defect in green tea gel group at 3 days. H&EX20

Figure 5: New blood vessels (arrow heads) in developing osteoid tissue. H&EX40

Figure 6: Trabeculated bone (TB), Coalesce with cutting bone (CB) in green tea gel group 7 days. H&EX20
Experimental group: Bone treated with extracted green tea gel illustrated osteoid tissue filled the bone defect with newly formed blood vessels is detected at 3 day Figures (4,5). Trabeculated bone, coalesce with cutting bone in extracted green tea gel group 7 days with highly vascular ostoid tissue; Figures (6,7) and the period 10 days illustrated new bone with multiple haverssian canal in nearby cutting bone; Figure (8).

3.2 Immunohistochemical evaluation for expression of bone morphogenic protein 2

Figure(9) Immunohistochemical view for control group 3 days shows positive bone morphogenic protein 2 expression by progenitor(arrow head), inflammatory cell (green arrow), endothelial cell (pink arrow). DAB stainX20.

Figure (10) Osteoprogenitor cell (arrow heads) and osteoblast (arrow) show positive BMP2 expression. DAB stainX40

Figure (11) Osteoblast (arrows), reticular cell (arrows heads) show positive BMP2 expression in control group 10 days. DAB stainX40

Figure(12) Immunohistchemical view for positive BMP2 expressed by osteoprogenitor cell (arrows) in green tea gel group 3 days. DAB stainX20

Figure (13) Osteoblast (arrows) and progenitor cell (arrow heads) expressed positive BMP2. DAB stainX40
Control group shows an immunohistochemical view shows positive BMP2 expression by progenitor cell, inflammatory cell and endothelial cell in control group 3 days (Figure 9). Osteoprogenitor cell and osteoblast show positive BMP2 expression at 7 day (Figure 10). Osteoblast and reticular cell show positive BMP2 expression at 10 day (Figure 11).

Experimental group of extracted green tea gel illustrates an immunohistochemical view for positive BMP2 expressed by progenitor cell and endothelial cell in green tea gel group 3 days (Figure 12). Osteoblast and reticular cell show positive BMP2 expression at 7 day (Figure 13). Haversian canal (HC) content and active osteocyte in green tea gel 10 days show positive BMP2 expression (Figure 14).

Statistical analysis of results

Results for the mean of bone cells count at 7 period for all study groups illustrates a high significant difference value for green tea gel group in comparism to control group.

It has been shown that at 7 days duration the mean of the no. of osteoblast cells was significantly higher (18.23) P<0.001 in the study group treated with green tea gel. The mean of the no. of osteocyte cells was significantly higher (15.25) P<0.001 in the study group treated with green tea gel at 7 days duration. The mean of no. of osteoclast cells was significantly higher (1.88) P<0.001 in the study group treated with green tea gel at 7 days duration.

Table 2,3 show the statistics and duration difference of the positive stromal cells expressed bone morphogenic protein 2 and it represents a highly significant difference values for green tea gel group in comparism to control group.

DISCUSSION

Bone formation is a continuous process that begins during fetal development and persis throughout life as a remodeling process. In the event of injury, bones heal by generating new bone rather scar tissue (Carvalhol et al., 2012), to elucidate the extent to which skeletal regeneration affected by exogenous extracted green tea gel, we used detailed expression stages of bone apposition and ossification.

The present study shows an early ostoid deposition in extracted green tea gel group at 3 day period, as ostoid tissue formation, accompanied with significant immunopositive expression for bone morphogenic protein 2 in bone defect site. These results could be attributed to, that the traumatic site includes, stem cells differentiate into osteoblasts (Catharino et al., 2014) that enhanced by bone morphogenic protein 2 which has been implicated in angiogenesis and the proliferative osteoblast and active osteocyte were included in deposition of collagen fiber.

At 7&10 day periods, extracted green tea gel groups show trabeculae filled a proximately the whole defect in comparism to histologic views for control group. This result can be attributed that green tea gel directly promotes the differentiation of primary osteoblast, which is responsible for bone apposition and mineralization. The placebo-treated defects were not able to create a bony bridge across the gap. In contrast, green tea gel treatment caused significant filling with bone.

The present statistics analysis for the mean value of osteoblast, active osteocyte in green tea gel group, and stromal cells that expressed immunopositive reaction for bone morphogenic protein 2 were
recorded to be a highly significant differences in comparison to control group.

By direct exposing the extracted green tea gel to bone defect, bone-forming cells from rats — called osteoblasts — to these green tea compounds, the research found that both the rate of bone growth and bone strengthening was significantly increased within a few days.

Some of this bone boosting affect comes down to the activity of a key enzyme that promotes bone growth. One particular green tea compound called Epi-gallo-catechin (EGC), led to an increase in this enzyme’s activity by 79%. It also increased levels of bone mineralization in these cells: a vital part of strengthening bones. Epi-gallo-catechin also suppressed the activity of cells called osteoclast cells that weaken and break down old bone, part of the natural process of bone remodelling. This study was conducted on rat bone cells, so further research is need to see if the same affect will hold true for human bone cells, this is acoincided with Chun et al.,2009 who was founded that catechin compound that present in green tea increase the harnessed of osteoporotic bone.

Our study shown that polyphenols which present in green tea (GTP) have positive effects on bone healing, this coincide with Shen et al.,2008 who stated that the GTP prevented the aging-induced as well as aging plus estrogen deficiency-induced reduction in femoral bone mass.
